Substring search

Goal. Find pattern of length M in a text of length N .

pattern → N E E D L E
text → I N A H A Y S T A C K N E E D L E I N A

↑
match

typically $N \gg M$

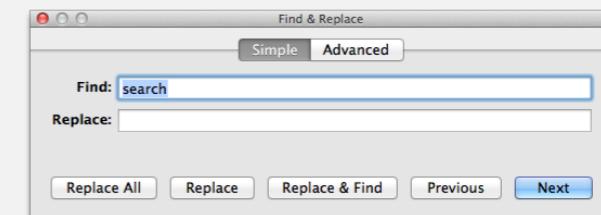

Substring search applications

Goal. Find pattern of length M in a text of length N .

pattern → N E E D L E
text → I N A H A Y S T A C K N E E D L E I N A

↑
match

typically $N \gg M$

Substring search applications

Goal. Find pattern of length M in a text of length N .

typically $N \gg M$

pattern → N E E D L |

Computer forensics. Search memory or disk for signatures, e.g., all URLs or RSA keys that the user has entered.

<http://citr.princeton.edu/memory>

5

Substring search applications

Goal. Find pattern of length M in a text of length N .

typically $N \gg M$

pattern → N E E D L E

6

Substring search applications

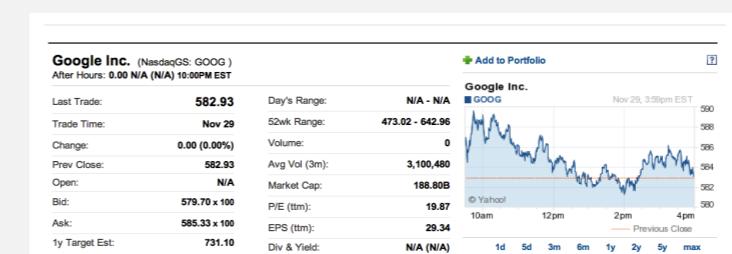

Electronic surveillance.

Substring search applications

Screen scraping. Extract relevant data from web page.

Ex. Find string delimited by and after first occurrence of pattern Last Trade::

<http://finance.yahoo.com/q?s=goog>

```
...
<tr>
<td class= "yfnc_tablehead1"
width= "48%">
Last Trade:
</td>
<td class= "yfnc_tabledata1">
<big><b>452.92</b></big>
</td></tr>
<td class= "yfnc_tablehead1"
width= "48%">
Trade Time:
</td>
<td class= "yfnc_tabledata1">
...
```

7

8

Screen scraping: Java implementation

Java library. The `indexOf()` method in Java's string library returns the index of the first occurrence of a given string, starting at a given offset.

```
public class StockQuote
{
    public static void main(String[] args)
    {
        String name = "http://finance.yahoo.com/q?s=";
        In in = new In(name + args[0]);
        String text = in.readAll();
        int start    = text.indexOf("Last Trade:", 0);
        int from     = text.indexOf("<b>", start);
        int to       = text.indexOf("</b>", from);
        String price = text.substring(from + 3, to);
        StdOut.println(price);
    }
}

% java StockQuote goog
582.93

% java StockQuote msft
24.84
```

5.3 SUBSTRING SEARCH

- ▶ introduction
- ▶ brute force
- ▶ Knuth-Morris-Pratt
- ▶ Boyer-Moore
- ▶ Rabin-Karp

Brute-force substring search

Check for pattern starting at each text position.

Brute-force substring search: Java implementation

Check for pattern starting at each text position.

i	j	i+j	0	1	2	3	4	5	6	7	8	9	10
			A	B	A	C	A	D	A	B	R	A	C
4	3	7											
5	0	5											

```
public static int search(String pat, String txt)
{
    int M = pat.length();
    int N = txt.length();
    for (int i = 0; i <= N - M; i++)
    {
        int j;
        for (j = 0; j < M; j++)
            if (txt.charAt(i+j) != pat.charAt(j))
                break;
        if (j == M) return i; ← index in text where pattern starts
    }
    return N; ← not found
}
```

11

12

Brute-force substring search: worst case

Brute-force algorithm can be slow if text and pattern are repetitive.

Worst case. $\sim M N$ char compares.

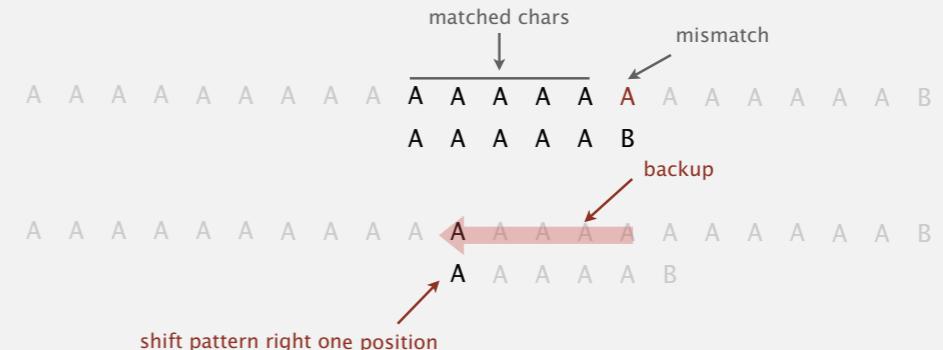

Backup

In many applications, we want to avoid **backup** in text stream.

- Treat input as stream of data.
 - Abstract model: standard input.

Brute-force algorithm needs backup for every mismatch.

Approach 1. Maintain buffer of last M characters.

Approach 2. Stay tuned.

Brute-force substring search: alternate implementation

Same sequence of char compares as previous implementation.

- i points to end of sequence of already-matched chars in text.
 - i stores # of already-matched chars (end of sequence in pattern).

i	j	0	1	2	3	4	5	6	7	8	9	10
		A	B	A	C	A	D	A	B	R	A	C
7	3					A	D	A	C	R		
5	0						A	D	A	C	R	

```
public static int search(String pat, String txt)
{
    int i, N = txt.length();
    int j, M = pat.length();
    for (i = 0, j = 0; i < N && j < M; i++)
    {
        if (txt.charAt(i) == pat.charAt(j)) j++;
        else { i -= j; j = 0; }                                ← explicit backup
    }
    if (j == M) return i - M;
    else         return N;
}
```

Algorithmic challenges in substring search

Brute-force is not always good enough.

Theoretical challenge. Linear-time guarantee.

Practical challenge. Avoid backup in text stream. ← often no room or time to save text

Now is the time for all people to come to the aid of their party. Now is the time for all good people to come to the aid of their party. Now is the time for many good people to come to the aid of their party. Now is the time for all good people to come to the aid of their party. Algorithms

5.3 SUBSTRING SEARCH

- ▶ introduction
- ▶ brute force
- ▶ Knuth-Morris-Pratt
- ▶ Boyer-Moore
- ▶ Rabin-Karp

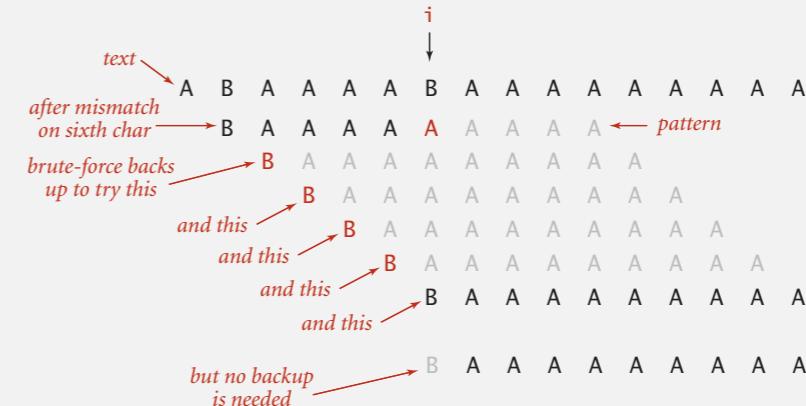

ROBERT SEDGEWICK | KEVIN WAYNE
<http://algs4.cs.princeton.edu>

Knuth-Morris-Pratt substring search

Intuition. Suppose we are searching in text for pattern BAAAAAAA.

- Suppose we match 5 chars in pattern, with mismatch on 6th char.
- We know previous 6 chars in text are BAAAB.
- Don't need to back up text pointer!

assuming { A, B } alphabet

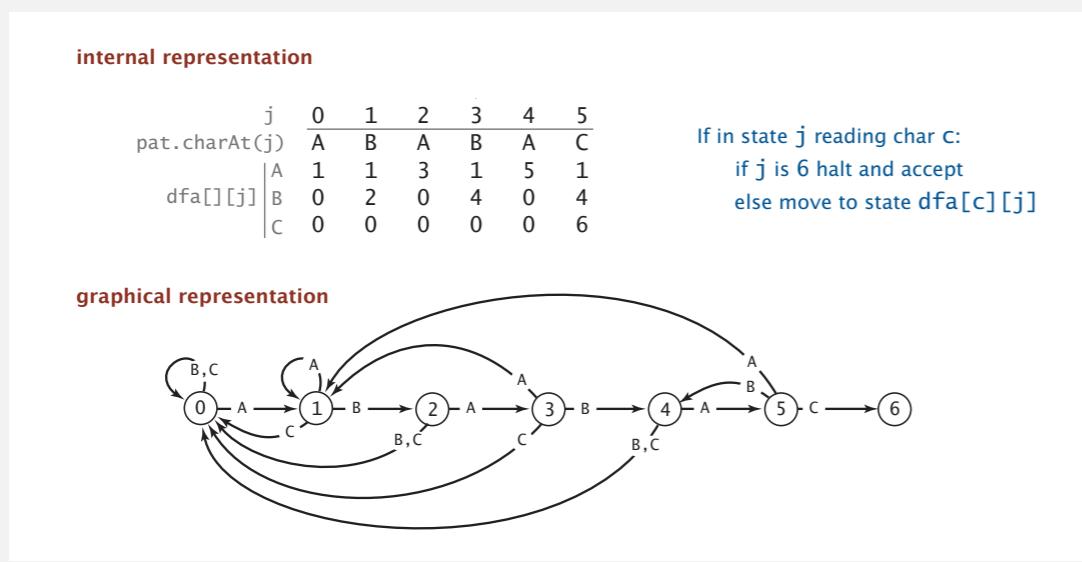

Knuth-Morris-Pratt algorithm. Clever method to always avoid backup. (!)

18

Deterministic finite state automaton (DFA)

DFA is abstract string-searching machine.

- Finite number of states (including start and halt).
- Exactly one transition for each char in alphabet.
- Accept if sequence of transitions leads to halt state.

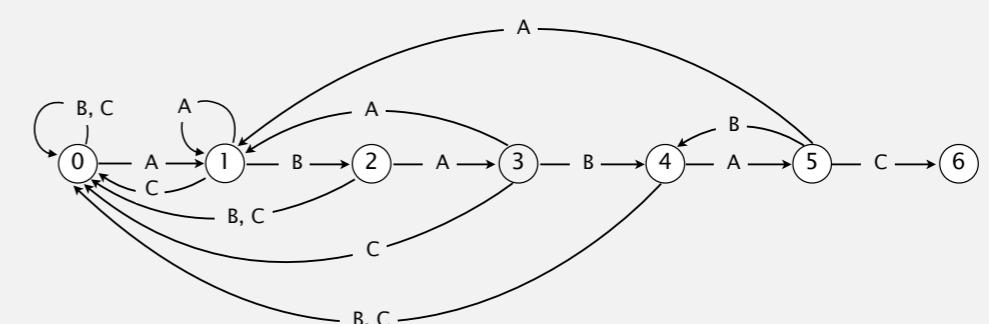

Knuth-Morris-Pratt demo: DFA simulation

A A B A C A A B A B A C A A

	0	1	2	3	4	5
pat.charAt(j)	A	B	A	B	A	C
A	1	1	3	1	5	1
dfa[][][j]	B	0	2	0	4	0
C	0	0	0	0	0	6

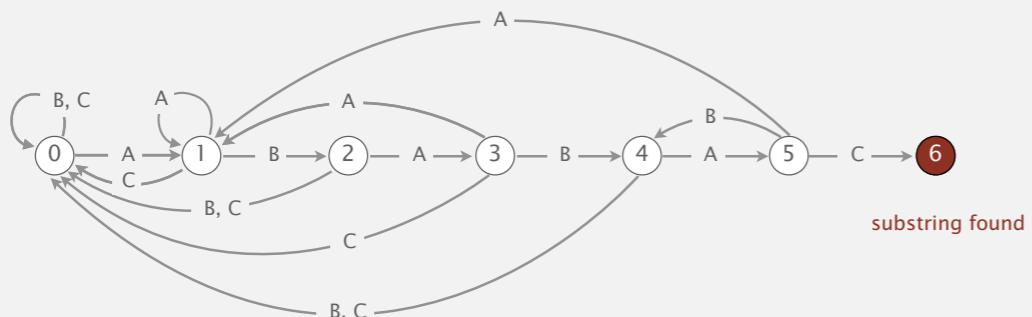

19

20

Knuth-Morris-Pratt demo: DFA simulation

A A B A C A A B A B A C A A
↑

	0	1	2	3	4	5
pat.charAt(j)	A	B	A	B	A	C
dfa[][][j]	A	1	1	3	1	5
	B	0	2	0	4	0
	C	0	0	0	0	6

21

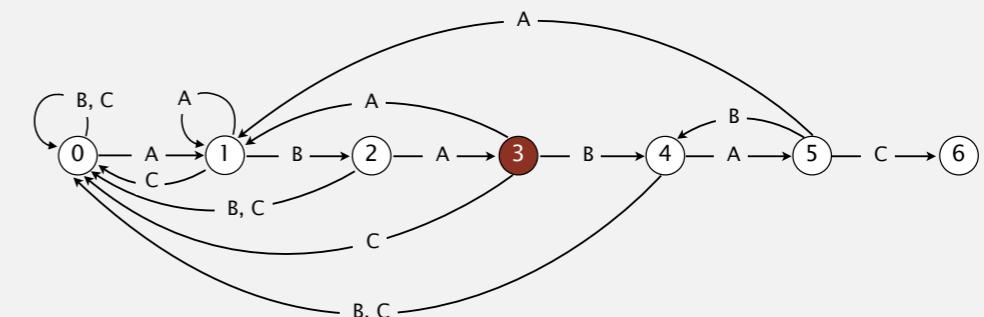

Interpretation of Knuth-Morris-Pratt DFA

Q. What is interpretation of DFA state after reading in $\text{txt}[i]$?

A. State = number of characters in pattern that have been matched.

length of longest prefix of $\text{pat}[]$
that is a suffix of $\text{txt}[0..i]$

Ex. DFA is in state 3 after reading in $\text{txt}[0..6]$.

22

Knuth-Morris-Pratt substring search: Java implementation

Key differences from brute-force implementation.

- Need to precompute $\text{dfa}[][]$ from pattern.
- Text pointer i never decrements.

```
public int search(String txt)
{
    int i, j, N = txt.length();
    for (i = 0, j = 0; i < N && j < M; i++)
        j = dfa[txt.charAt(i)][j];           ← no backup
    if (j == M) return i - M;
    else        return N;
}
```

Running time.

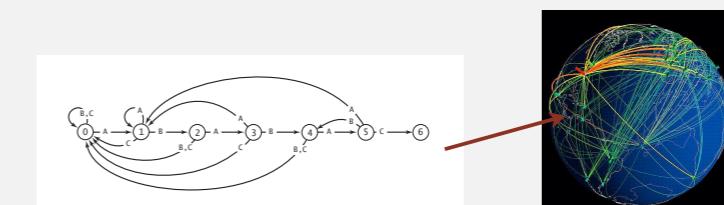

- Simulate DFA on text: at most N character accesses.
- Build DFA: how to do efficiently? [warning: tricky algorithm ahead]

23

Key differences from brute-force implementation.

- Need to precompute $\text{dfa}[][]$ from pattern.
- Text pointer i never decrements.
- Could use **input stream**.

```
public int search(In in)
{
    int i, j;
    for (i = 0, j = 0; !in.isEmpty() && j < M; i++)
        j = dfa[in.readChar()][j];           ← no backup
    if (j == M) return i - M;
    else        return NOT_FOUND;
}
```

24

Knuth-Morris-Pratt demo: DFA construction

Include one state for each character in pattern (plus accept state).

pat.charAt(j)	0	1	2	3	4	5
dfa[j][j]	A	B	A	B	A	C
	A	B	C			

Constructing the DFA for KMP substring search for A B A B A C

25

How to build DFA from pattern?

Include one state for each character in pattern (plus accept state).

pat.charAt(j)	0	1	2	3	4	5
dfa[j][j]	A	B	A	B	A	C
	A	B	C			

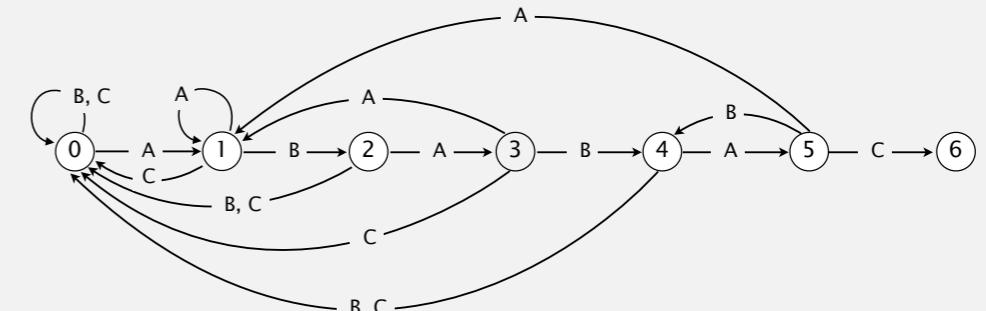

27

Knuth-Morris-Pratt demo: DFA construction

pat.charAt(j)	0	1	2	3	4	5
dfa[j][j]	A	B	A	B	A	C
	A	B	C			

Constructing the DFA for KMP substring search for A B A B A C

26

How to build DFA from pattern?

Match transition. If in state j and next char c == pat.charAt(j), go to j+1.

first j characters of pattern have already been matched

next char matches

now first j + 1 characters of pattern have been matched

pat.charAt(j)	0	1	2	3	4	5
dfa[j][j]	A	B	A	B	A	C
	A	B	C			

28

How to build DFA from pattern?

Mismatch transition. If in state j and next char $c \neq \text{pat.charAt}(j)$, then the last $j-1$ characters of input are $\text{pat}[1..j-1]$, followed by c .

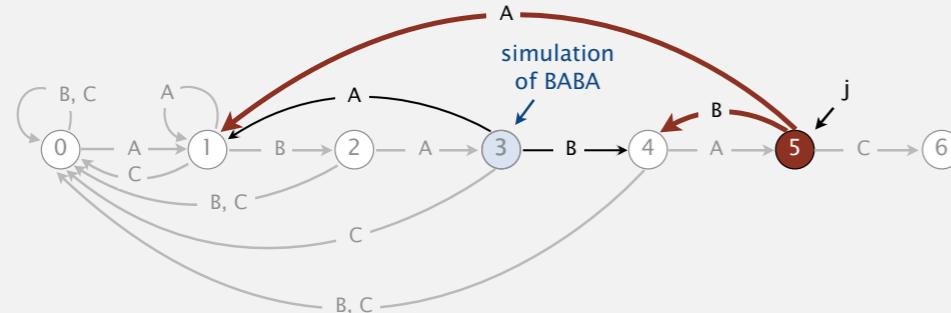

To compute $\text{dfa}[c][j]$: Simulate $\text{pat}[1..j-1]$ on DFA and take transition c .
Running time. Seems to require j steps.

Ex. $\text{dfa}['A'][5] = 1; \text{dfa}['B'][5] = 4$

simulate BABA;
take transition 'A'
 $= \text{dfa}['A'][3]$

simulate BABA;
take transition 'B'
 $= \text{dfa}['B'][3]$

$\text{pat.charAt}(j) \quad j \quad 0 \quad 1 \quad 2 \quad 3 \quad 4 \quad 5$
A B A B A C

29

How to build DFA from pattern?

Mismatch transition. If in state j and next char $c \neq \text{pat.charAt}(j)$, then the last $j-1$ characters of input are $\text{pat}[1..j-1]$, followed by c .

To compute $\text{dfa}[c][j]$: Simulate $\text{pat}[1..j-1]$ on DFA and take transition c .
Running time. Takes only constant time if we maintain state X .

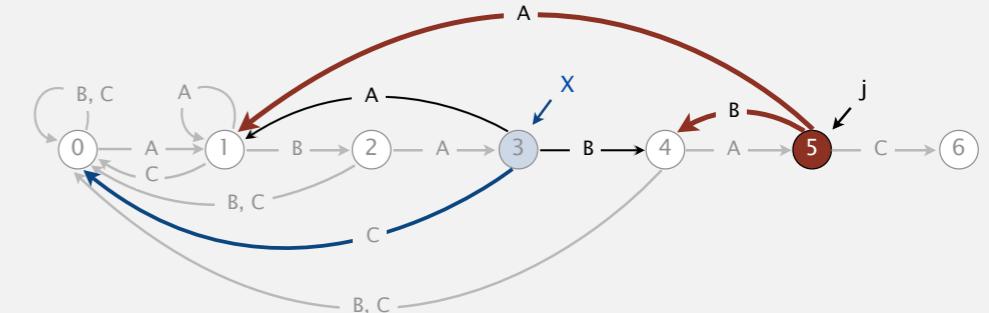

Ex. $\text{dfa}['A'][5] = 1; \text{dfa}['B'][5] = 4 \quad X' = 0$

from state X ,
take transition 'A'
 $= \text{dfa}['A'][X]$

from state X ,
take transition 'B'
 $= \text{dfa}['B'][X]$

from state X ,
take transition 'C'
 $= \text{dfa}['C'][X]$

$0 \quad 1 \quad 2 \quad 3 \quad 4 \quad 5$
A B A B A C

30

Knuth-Morris-Pratt demo: DFA construction in linear time

Include one state for each character in pattern (plus accept state).

$\text{pat.charAt}(j)$	0	1	2	3	4	5
$\text{pat.charAt}(j)$	A	B	A	B	A	C
$\text{dfa}[] [j]$	A	B				
	0	1	2	3	4	5

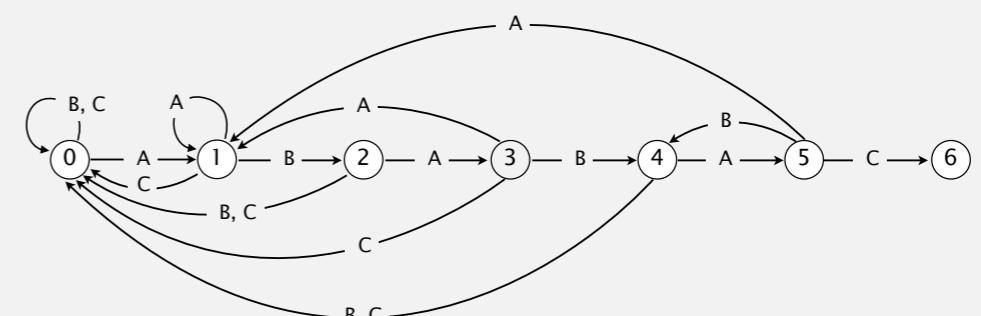

Constructing the DFA for KMP substring search for A B A B A C

(0) (1) (2) (3) (4) (5) (6)

Knuth-Morris-Pratt demo: DFA construction in linear time

$\text{pat.charAt}(j)$	0	1	2	3	4	5
$\text{pat.charAt}(j)$	A	B	A	B	A	C
$\text{dfa}[] [j]$	A	1	1	3	1	5
	0	2	0	4	0	4
	0	0	0	0	0	6

Constructing the DFA for KMP substring search for A B A B A C

31

32

Constructing the DFA for KMP substring search: Java implementation

For each state j :

- Copy $\text{dfa}[][][X]$ to $\text{dfa}[][][j]$ for mismatch case.
- Set $\text{dfa}[\text{pat.charAt}(j)][j]$ to $j+1$ for match case.
- Update X .

```
public KMP(String pat)
{
    this.pat = pat;
    M = pat.length();
    dfa = new int[R][M];
    dfa[pat.charAt(0)][0] = 1;
    for (int X = 0, j = 1; j < M; j++)
    {
        for (int c = 0; c < R; c++)
            dfa[c][j] = dfa[c][X]; ← copy mismatch cases
        dfa[pat.charAt(j)][j] = j+1; ← set match case
        X = dfa[pat.charAt(j)][X]; ← update restart state
    }
}
```

Running time. M character accesses (but space/time proportional to $R M$).

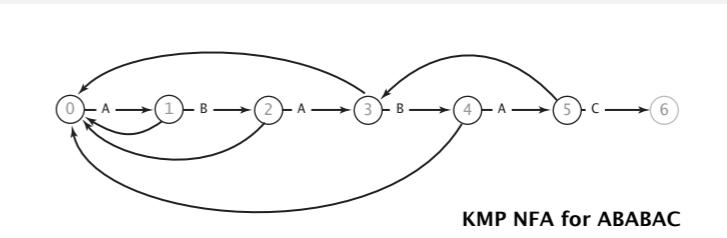

KMP substring search analysis

Proposition. KMP substring search accesses no more than $M + N$ chars to search for a pattern of length M in a text of length N .

Pf. Each pattern char accessed once when constructing the DFA; each text char accessed once (in the worst case) when simulating the DFA.

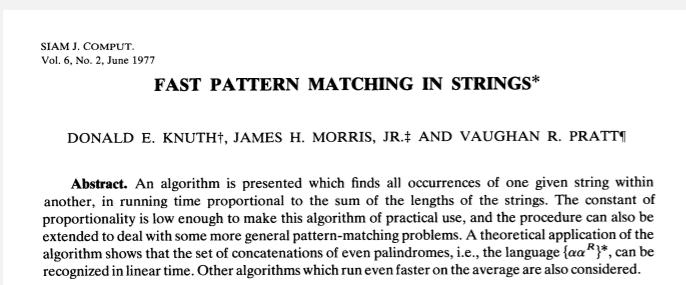

Proposition. KMP constructs $\text{dfa}[][]$ in time and space proportional to $R M$.

Larger alphabets. Improved version of KMP constructs $\text{nfa}[]$ in time and space proportional to M .

Knuth-Morris-Pratt: brief history

- Independently discovered by two theoreticians and a hacker.
 - Knuth: inspired by esoteric theorem, discovered linear algorithm
 - Pratt: made running time independent of alphabet size
 - Morris: built a text editor for the CDC 6400 computer
- Theory meets practice.

Don Knuth

Jim Morris

Vaughan Pratt

▶ Rabin-Karp

Robert Boyer

J. Strother Moore

Boyer-Moore: mismatched character heuristic

Intuition.

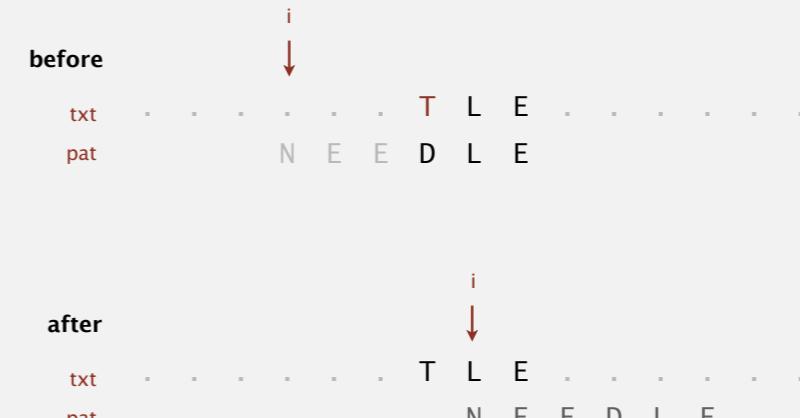

- Scan characters in pattern from right to left.
- Can skip as many as M text chars when finding one not in the pattern.

Boyer-Moore: mismatched character heuristic

Q. How much to skip?

Case 1. Mismatch character not in pattern.

mismatch character 'T' not in pattern: increment i one character beyond 'T'

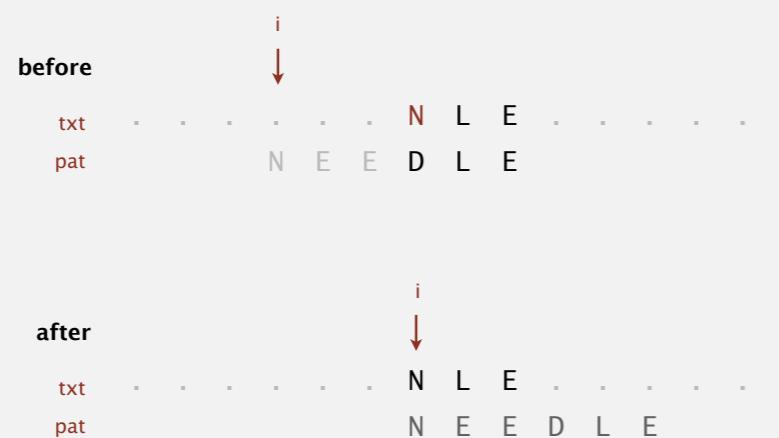

37

38

Boyer-Moore: mismatched character heuristic

Q. How much to skip?

Case 2a. Mismatch character in pattern.

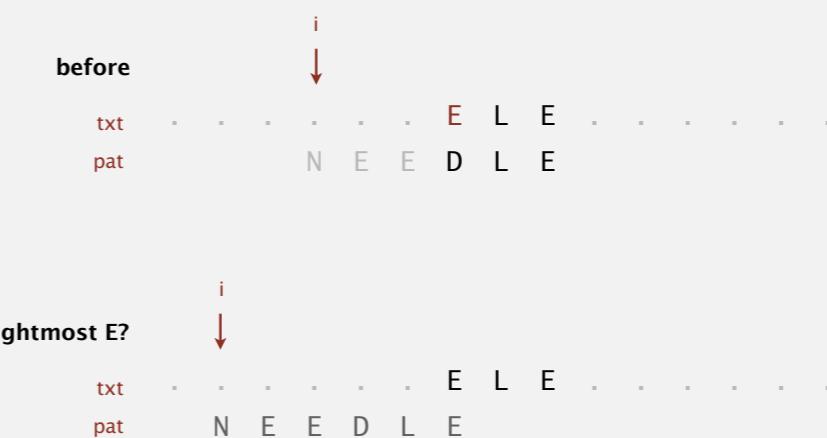

mismatch character 'N' in pattern: align text 'N' with rightmost pattern 'N'

Boyer-Moore: mismatched character heuristic

Q. How much to skip?

Case 2b. Mismatch character in pattern (but heuristic no help).

mismatch character 'E' in pattern: align text 'E' with rightmost pattern 'E' ?

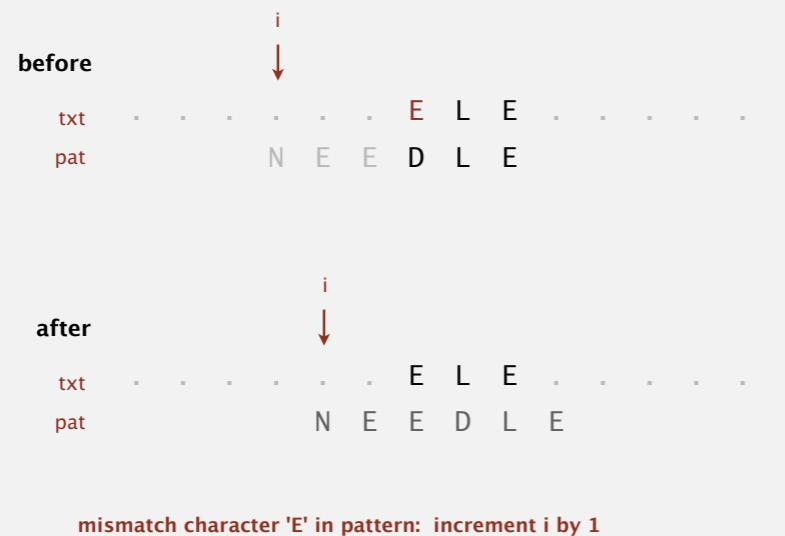

39

40

Boyer-Moore: mismatched character heuristic

Q. How much to skip?

Case 2b. Mismatch character in pattern (but heuristic no help).

Boyer-Moore: mismatched character heuristic

Q. How much to skip?

- A. Precompute index of rightmost occurrence of character c in pattern.
(-1 if character not in pattern)

c	N	E	E	D	L	E	right[c]
A	-1	-1	-1	-1	-1	-1	-1
B	-1	-1	-1	-1	-1	-1	-1
C	-1	-1	-1	-1	-1	-1	-1
D	-1	-1	-1	-1	③	3	3
E	-1	-1	①	②	2	2	5
...							
L	-1	-1	-1	-1	-1	④	4
M	-1	-1	-1	-1	-1	-1	-1
N	-1	0	0	0	0	0	0
...							

Boyer-Moore skip table computation

Boyer-Moore: Java implementation

```
public int search(String txt)
{
    int N = txt.length();
    int M = pat.length();
    int skip;
    for (int i = 0; i <= N-M; i += skip)
    {
        skip = 0;
        for (int j = M-1; j >= 0; j--)
        {
            if (pat.charAt(j) != txt.charAt(i+j))
            {
                skip = Math.max(1, j - right[txt.charAt(i+j)]);
                break;
            }
        }
        if (skip == 0) return i; ← match
    }
    return N;
}
```

compute skip value

in case other term is nonpositive

Boyer-Moore: analysis

Property. Substring search with the Boyer-Moore mismatched character heuristic takes about $\sim N/M$ character compares to search for a pattern of length M in a text of length N . sublinear!

Worst-case. Can be as bad as $\sim MN$.

i	skip	0	1	2	3	4	5	6	7	8	9
	txt →	B	B	B	B	B	B	B	B	B	B
0	0	A	B	B	B	B	B	B	B	B	B
1	1		A	B	B	B	B				
2	1			A	B	B	B	B			
3	1				A	B	B	B	B		
4	1					A	B	B	B	B	
5	1						A	B	B	B	B

Boyer-Moore variant. Can improve worst case to $\sim 3N$ character compares by adding a KMP-like rule to guard against repetitive patterns.

Algorithms

5.3 SUBSTRING SEARCH

- ▶ introduction
- ▶ brute force
- ▶ Knuth-Morris-Pratt
- ▶ Boyer-Moore
- ▶ Rabin-Karp

Michael Rabin
Dick Karp

Rabin-Karp fingerprint search

Basic idea = modular hashing.

- Compute a hash of $\text{pat}[0..M-1]$.
- For each i , compute a hash of $\text{txt}[i..M+i-1]$.
- If pattern hash = text substring hash, check for a match.

$\text{pat}.\text{charAt}(i)$																	
i	0	1	2	3	4												
	2	6	5	3	5												
$\% 997 = 613$																	
$\text{txt}.\text{charAt}(i)$																	
i	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
	3	1	4	1	5	9	2	6	5	3	5	8	9	7	9	3	
0	3	1	4	1	5	$\% 997 = 508$											
1		1	4	1	5	9	$\% 997 = 201$										
2			4	1	5	9	2	$\% 997 = 715$									
3				1	5	9	2	6	$\% 997 = 971$								
4					5	9	2	6	5	$\% 997 = 442$							
5						9	2	6	5	3	$\% 997 = 929$						
6							2	6	5	3	5	$\% 997 = 613$					

modular hashing with $R = 10$ and $\text{hash}(s) = s \pmod{997}$

Modular arithmetic

Math trick. To keep numbers small, take intermediate results modulo Q .

$$\begin{aligned} \text{Ex. } & (10000 + 535) * 1000 \pmod{997} \\ &= (30 + 535) * 3 \pmod{997} \\ &= 1695 \pmod{997} \\ &= 698 \pmod{997} \end{aligned}$$

$$(a + b) \pmod{Q} = ((a \pmod{Q}) + (b \pmod{Q})) \pmod{Q}$$

$$(a * b) \pmod{Q} = ((a \pmod{Q}) * (b \pmod{Q})) \pmod{Q}$$

two useful modular arithmetic identities

Efficiently computing the hash function

Modular hash function. Using the notation t_i for $\text{txt}.\text{charAt}(i)$, we wish to compute

$$x_i = t_i R^{M-1} + t_{i+1} R^{M-2} + \dots + t_{i+M-1} R^0 \pmod{Q}$$

Intuition. M -digit, base- R integer, modulo Q .

Horner's method. Linear-time method to evaluate degree- M polynomial.

$\text{pat}.\text{charAt}(i)$							
i	0	1	2	3	4		
	2	6	5	3	5		
0	2	$\% 997 = 2$					
1	2	6	$\% 997 = (2 * 10 + 6) \pmod{997} = 26$				
2	2	6	5	$\% 997 = (26 * 10 + 5) \pmod{997} = 265$			
3	2	6	5	3	$\% 997 = (265 * 10 + 3) \pmod{997} = 659$		
4	2	6	5	3	5	$\% 997 = (659 * 10 + 5) \pmod{997} = 613$	

```
// Compute hash for M-digit key
private long hash(String key, int M)
{
    long h = 0;
    for (int j = 0; j < M; j++)
        h = (h * R + key.charAt(j)) % Q;
    return h;
}
```

$$\begin{aligned} 26535 &= 2 * 10000 + 6 * 1000 + 5 * 100 + 3 * 10 + 5 \\ &= (((2 * 10 + 6) * 10 + 5) * 10 + 3) * 10 + 5 \end{aligned}$$

Efficiently computing the hash function

Challenge. How to efficiently compute x_{i+1} given that we know x_i .

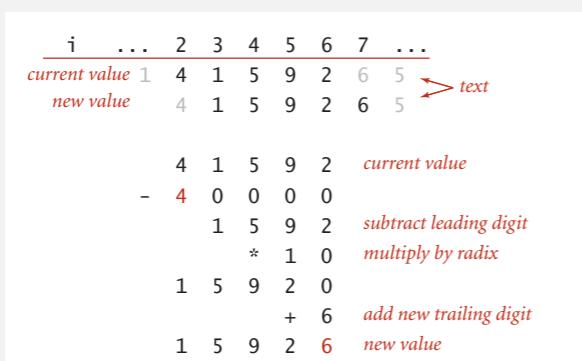

$$x_i = t_i R^{M-1} + t_{i+1} R^{M-2} + \dots + t_{i+M-1} R^0$$

$$x_{i+1} = t_{i+1} R^{M-1} + t_{i+2} R^{M-2} + \dots + t_{i+M} R^0$$

Key property. Can update "rolling" hash function in constant time!

$$x_{i+1} = (x_i - t_i R^{M-1}) R + t_{i+M}$$

↑ current value ↑ subtract leading digit ↑ multiply by radix ↑ add new trailing digit (can precompute R^{M-1})

Rabin-Karp substring search example

First R entries: Use Horner's rule.

Remaining entries: Use rolling hash (and % to avoid overflow).

i	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
	3	1	4	1	5	9	2	6	5	3	5	8	9	7	9	3
0	3	% 997	= 3													
1	3	1	% 997	= (3*10 + 1) % 997	= 31											
2	3	1	4	% 997	= (31*10 + 4) % 997	= 314										
3	3	1	4	1	% 997	= (314*10 + 1) % 997	= 150									
4	3	1	4	1	5	% 997	= (150*10 + 5) % 997	= 508	RM	R						
5	1	4	1	5	9	% 997	= ((508 + 3*(997 - 30))*10 + 9) % 997	= 201								
6	4	1	5	9	2	% 997	= ((201 + 1*(997 - 30))*10 + 2) % 997	= 715								
7	1	5	9	2	6	% 997	= ((715 + 4*(997 - 30))*10 + 6) % 997	= 971								
8	5	9	2	6	5	% 997	= ((971 + 1*(997 - 30))*10 + 5) % 997	= 442								
9	9	2	6	5	3	% 997	= ((442 + 5*(997 - 30))*10 + 3) % 997	= 929								
10	2	6	5	3	5	% 997	= ((929 + 9*(997 - 30))*10 + 5) % 997	= 613								

Horner's rule rolling hash

match

-30 (mod 997) = 997 - 30 10000 (mod 997) = 30

Rabin-Karp: Java implementation

```
public class RabinKarp
{
    private long patHash; // pattern hash value
    private int M; // pattern length
    private long Q; // modulus
    private int R; // radix
    private long RM1; // R^(M-1) % Q

    public RabinKarp(String pat) {
        M = pat.length();
        R = 256;
        Q = LongRandomPrime(); // a large prime (but avoid overflow)
        RM1 = 1;
        for (int i = 1; i <= M-1; i++)
            RM1 = (R * RM1) % Q;
        patHash = hash(pat, M);
    }

    private long hash(String key, int M)
    { /* as before */ }

    public int search(String txt)
    { /* see next slide */ }
}
```

← a large prime (but avoid overflow)

← precompute $R^{M-1} \pmod{Q}$

Rabin-Karp: Java implementation (continued)

Monte Carlo version. Return match if hash match.

```
public int search(String txt)
{
    int N = txt.length();
    int txtHash = hash(txt, M);
    if (patHash == txtHash) return 0;
    for (int i = M; i < N; i++)
    {
        txtHash = (txtHash + Q - RM1*txt.charAt(i-M) % Q) % Q;
        txtHash = (txtHash*R + txt.charAt(i)) % Q;
        if (patHash == txtHash) return i - M + 1;
    }
    return N;
}
```

check for hash collision using rolling hash function

Las Vegas version. Check for substring match if hash match; continue search if false collision.

51

52

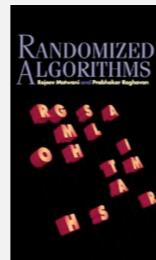

Rabin-Karp analysis

Theory. If Q is a sufficiently large random prime (about MN^2), then the probability of a false collision is about $1/N$.

Practice. Choose Q to be a large prime (but not so large to cause overflow). Under reasonable assumptions, probability of a collision is about $1/Q$.

Monte Carlo version.

- Always runs in linear time.
- Extremely likely to return correct answer (but not always!).

Las Vegas version.

- Always returns correct answer.
- Extremely likely to run in linear time (but worst case is MN).

Rabin-Karp fingerprint search

Advantages.

- Extends to 2d patterns.
- Extends to finding multiple patterns.

Disadvantages.

- Arithmetic ops slower than char compares.
- Las Vegas version requires backup.
- Poor worst-case guarantee.

Q. How would you extend Rabin-Karp to efficiently search for any one of P possible patterns in a text of length N ?

Substring search cost summary

Cost of searching for an M -character pattern in an N -character text.

algorithm	version	operation count guarantee	operation count typical	backup in input?	correct?	extra space
brute force	—	MN	$1.1N$	yes	yes	1
Knuth-Morris-Pratt	full DFA (Algorithm 5.6)	$2N$	$1.1N$	no	yes	MR
	mismatch transitions only	$3N$	$1.1N$	no	yes	M
Boyer-Moore	full algorithm	$3N$	N/M	yes	yes	R
Boyer-Moore	mismatched char heuristic only (Algorithm 5.7)	MN	N/M	yes	yes	R
Rabin-Karp [†]	Monte Carlo (Algorithm 5.8)	$7N$	$7N$	no	yes [‡]	1
	Las Vegas	$7N^\dagger$	$7N$	yes	yes	1

[‡] probabilistic guarantee, with uniform hash function
